4.2 The Mean Value Theorem

We know that constant functions have zero derivatives, but could there be a complicated function, with many terms, the derivatives of which all cancel to give zero? What is the relationship between two functions that have identical derivatives over an interval? What we are really asking here is what functions can have a particular kind of derivative. These and many other questions we study in this chapter are answered by applying the Mean Value Theorem. To arrive at this theorem we first need Rolle's Theorem.

**Rolle's Theorem**

Drawing the graph of a function gives strong geometric evidence that between any two points where a differentiable function crosses a horizontal line there is at least one point on the curve where the tangent is horizontal (Figure 4.10). More precisely, we have the following theorem.

**THEOREM 3 Rolle's Theorem**

Suppose that \( y = f(x) \) is continuous at every point of the closed interval \([a, b]\) and differentiable at every point of its interior \((a, b)\). If

\[
f(a) = f(b),
\]

then there is at least one number \( c \) in \((a, b)\) at which

\[
f'(c) = 0.
\]

**Proof** Being continuous, \( f \) assumes absolute maximum and minimum values on \([a, b]\). These can occur only
Chapter 4: Applications of Derivatives

Section 4.3: Mean Value Theorem and Its Applications

1. at interior points where \( f' \) is zero,
2. at interior points where \( f' \) does not exist,
3. at the endpoints of the function’s domain, in this case \( a \) and \( b \).

By hypothesis, \( f \) has a derivative at every interior point. That rules out possibility (2), leaving us with interior points where \( f' = 0 \) and with the two endpoints \( a \) and \( b \).

If either the maximum or the minimum occurs at a point \( c \) between \( a \) and \( b \), then by Theorem 2 in Section 4.1, and we have found a point for Rolle’s theorem.

If both the absolute maximum and the absolute minimum occur at the endpoints, then because it must be the case that \( f \) is a constant function with \( f'(x) = 0 \) for every \( x \in [a, b] \). Therefore \( f'(x) = 0 \) and the point \( c \) can be taken anywhere in the interior \((a, b)\).

The hypotheses of Theorem 3 are essential. If they fail at even one point, the graph may not have a horizontal tangent (Figure 4.11).

**FIGURE 4.11** There may be no horizontal tangent if the hypotheses of Rolle’s Theorem do not hold.

**EXAMPLE 1** Horizontal Tangents of a Cubic Polynomial

The polynomial function

\[
 f(x) = \frac{x^3}{3} - 3x
\]

graphed in Figure 4.12 is continuous at every point of \([-3, 3]\) and is differentiable at every point of \((-3, 3)\). Since \( f(-3) = f(3) = 0 \), Rolle’s Theorem says that \( f' \) must be zero at least once in the open interval between \( a = -3 \) and \( b = 3 \). In fact, \( f'(x) = x^2 - 3 \) is zero twice in this interval, once at \( x = -\sqrt{3} \) and again at \( x = \sqrt{3} \).

**EXAMPLE 2** Solution of an Equation \( f(x) = 0 \)

Show that the equation

\[
 x^3 + 3x + 1 = 0
\]

has exactly one real solution.

**Solution** Let

\[
 y = f(x) = x^3 + 3x + 1.
\]

Then the derivative

\[
 f'(x) = 3x^2 + 3
\]
4.2 The Mean Value Theorem

The function \( f \) is never zero (because it is always positive). Now, if there were even two points \( x = a \) and \( x = b \) where \( f(x) \) was zero, Rolle’s Theorem would guarantee the existence of a point \( x = c \) in between where \( f' \) was zero. Therefore, \( f \) has no more than one zero. It does in fact have one zero, because the Intermediate Value Theorem tells us that the graph of \( y = f(x) \) crosses the \( x \)-axis somewhere between \( x = -1 \) (where \( y = -3 \)) and \( x = 0 \) (where \( y = 1 \)). (See Figure 4.13.)

Our main use of Rolle’s Theorem is in proving the Mean Value Theorem.

The Mean Value Theorem

The Mean Value Theorem, which was first stated by Joseph-Louis Lagrange, is a slanted version of Rolle’s Theorem (Figure 4.14). There is a point where the tangent is parallel to chord \( AB \).

**THEOREM 4 The Mean Value Theorem**

Suppose \( y = f(x) \) is continuous on a closed interval \([a, b]\) and differentiable on the interval’s interior \((a, b)\). Then there is at least one point \( c \) in \((a, b)\) at which

\[
\frac{f(b) - f(a)}{b - a} = f'(c).
\]  

(1)

**Proof** We picture the graph of \( f \) as a curve in the plane and draw a line through the points \( A(a, f(a)) \) and \( B(b, f(b)) \) (see Figure 4.15). The line is the graph of the function

\[
g(x) = f(a) + \frac{f(b) - f(a)}{b - a}(x - a)
\]  

(point-slope equation). The vertical difference between the graphs of \( f \) and \( g \) at \( x \) is

\[
h(x) = f(x) - g(x) = f(x) - f(a) - \frac{f(b) - f(a)}{b - a}(x - a).
\]  

(3)

Figure 4.16 shows the graphs of \( f, g \), and \( h \) together.

The function \( h \) satisfies the hypotheses of Rolle’s Theorem on \([a, b]\). It is continuous on \([a, b]\) and differentiable on \((a, b)\) because both \( f \) and \( g \) are. Also, \( h(a) = h(b) = 0 \) because the graphs of \( f \) and \( g \) both pass through \( A \) and \( B \). Therefore \( h'(c) = 0 \) at some point \( c \in (a, b) \). This is the point we want for Equation (1).

To verify Equation (1), we differentiate both sides of Equation (3) with respect to \( x \) and then set \( x = c \):

\[
h'(x) = f'(x) - \frac{f(b) - f(a)}{b - a}
\]  

Derivative of Eq. (3)…

\[
h'(c) = f'(c) - \frac{f(b) - f(a)}{b - a}
\]  

…with \( x = c \)

\[
0 = f'(c) - \frac{f(b) - f(a)}{b - a} \quad h'(c) = 0
\]  

Rearranged

\[
f'(c) = \frac{f(b) - f(a)}{b - a}.
\]
The hypotheses of the Mean Value Theorem do not require $f$ to be differentiable at either $a$ or $b$. Continuity at $a$ and $b$ is enough (Figure 4.17).

EXAMPLE 3  The function $f(x) = x^2$ (Figure 4.18) is continuous for $0 \leq x \leq 2$ and differentiable for $0 < x < 2$. Since $f(0) = 0$ and $f(2) = 4$, the Mean Value Theorem says that at some point $c$ in the interval, the derivative $f'(x) = 2x$ must have the value $(4 - 0)/(2 - 0) = 2$. In this (exceptional) case we can identify $c$ by solving the equation $2c = 2$ to get $c = 1$.

A Physical Interpretation

If we think of the number $(f(b) - f(a))/(b - a)$ as the average change in $f$ over $[a, b]$ and $f'(c)$ as an instantaneous change, then the Mean Value Theorem says that at some interior point the instantaneous change must equal the average change over the entire interval.

EXAMPLE 4  If a car accelerating from zero takes 8 sec to go 352 ft, its average velocity for the 8-sec interval is $352/8 = 44$ ft/sec. At some point during the acceleration, the Mean Value Theorem says, the speedometer must read exactly 30 mph (44 ft/sec) (Figure 4.19).

Mathematical Consequences

At the beginning of the section, we asked what kind of function has a zero derivative over an interval. The first corollary of the Mean Value Theorem provides the answer.

**COROLLARY 1  Functions with Zero Derivatives Are Constant**

If $f'(x) = 0$ at each point $x$ of an open interval $(a, b)$, then $f(x) = C$ for all $x \in (a, b)$, where $C$ is a constant.
4.2 The Mean Value Theorem

**Proof** We want to show that $f$ has a constant value on the interval $(a, b)$. We do so by showing that if $x_1$ and $x_2$ are any two points in $(a, b)$, then $f(x_1) = f(x_2)$. Numbering $x_1$ and $x_2$ from left to right, we have $x_1 < x_2$. Then $f$ satisfies the hypotheses of the Mean Value Theorem on $[x_1, x_2]$: It is differentiable at every point of $[x_1, x_2]$ and hence continuous at every point as well. Therefore,

$$
\frac{f(x_2) - f(x_1)}{x_2 - x_1} = f'(c)
$$

at some point $c$ between $x_1$ and $x_2$. Since $f' = 0$ throughout $(a, b)$, this equation translates successively into

$$
\frac{f(x_2) - f(x_1)}{x_2 - x_1} = 0,
$$

and $f(x_1) = f(x_2)$.

At the beginning of this section, we also asked about the relationship between two functions that have identical derivatives over an interval. The next corollary tells us that their values on the interval have a constant difference.

**COROLLARY 2** Functions with the Same Derivative Differ by a Constant

If $f'(x) = g'(x)$ at each point $x$ in an open interval $(a, b)$, then there exists a constant $C$ such that $f(x) = g(x) + C$ for all $x \in (a, b)$. That is, $f - g$ is a constant on $(a, b)$.

**Proof** At each point $x \in (a, b)$ the derivative of the difference function $h = f - g$ is

$$
h'(x) = f'(x) - g'(x) = 0.
$$

Thus, $h(x) = C$ on $(a, b)$ by Corollary 1. That is, $f(x) - g(x) = C$ on $(a, b)$, so $f(x) = g(x) + C$.

Corollaries 1 and 2 are also true if the open interval $(a, b)$ fails to be finite. That is, they remain true if the interval is $(a, \infty)$, $(-\infty, b)$, or $(-\infty, \infty)$.

Corollary 2 plays an important role when we discuss antiderivatives in Section 4.8. It tells us, for instance, that since the derivative of $f(x) = x^2$ on $(-\infty, \infty)$ is $2x$, any other function with derivative $2x$ on $(-\infty, \infty)$ must have the formula $x^2 + C$ for some value of $C$ (Figure 4.20).

**EXAMPLE 5** Find the function $f(x)$ whose derivative is $\sin x$ and whose graph passes through the point $(0, 2)$.

**Solution** Since $f(x)$ has the same derivative as $g(x) = -\cos x$, we know that $f(x) = -\cos x + C$ for some constant $C$. The value of $C$ can be determined from the condition that $f(0) = 2$ (the graph of $f$ passes through $(0, 2)$):

$$
f(0) = -\cos (0) + C = 2, \quad \text{so} \quad C = 3.
$$

The function is $f(x) = -\cos x + 3$.

**Finding Velocity and Position from Acceleration**

Here is how to find the velocity and displacement functions of a body falling freely from rest with acceleration $9.8 \text{ m/sec}^2$. 

---

Copyright © 2005 Pearson Education, Inc., publishing as Pearson Addison-Wesley
We know that $v(t)$ is some function whose derivative is 9.8. We also know that the derivative of $g(t) = 9.8t$ is 9.8. By Corollary 2,

$$v(t) = 9.8t + C$$

for some constant $C$. Since the body falls from rest, $v(0) = 0$. Thus

$$9.8(0) + C = 0, \quad \text{and} \quad C = 0.$$ 

The velocity function must be $v(t) = 9.8t$. How about the position function $s(t)$?

We know that $s(t)$ is some function whose derivative is 9.8. We also know that the derivative of $f(t) = 4.9t^2$ is 9.8. By Corollary 2,

$$s(t) = 4.9t^2 + C$$

for some constant $C$. If the initial height is $s(0) = h$, measured positive downward from the rest position, then

$$4.9(0)^2 + C = h, \quad \text{and} \quad C = h.$$ 

The position function must be $s(t) = 4.9t^2 + h$.

The ability to find functions from their rates of change is one of the very powerful tools of calculus. As we will see, it lies at the heart of the mathematical developments in Chapter 5.
